Status of Invasive Threats to Fruits and Vegetables in Minnesota

Plant Protection Division
Prepared February 2021
The Pathways Survey, funded by the United States Department of Agriculture (USDA) Plant Protection Act 7721 (formerly The Farm Bill), focuses on agricultural systems near urban areas, such as community gardens, fresh market produce farms, apple orchards, and vineyards. These areas are chosen because it maximizes opportunities for the early detection of new invasive species. In addition, high tunnels were surveyed for diseases of tomatoes, peppers, and cucumbers. These sites were chosen because high tunnels can be sheltered areas where invasive diseases have the potential to overwinter and become established. Some of our most important invasive species that are currently impacting Minnesota urban agricultural include brown marmorated stinkbug, club root, and Swede midge. These invasive species were first found in urban areas before spreading into more rural areas of the state. Thus, agricultural systems in and around urban areas can be thought of as part of a system of pathways by which invasive species become established and can spread.

Urban agricultural systems make good survey sites due to the high diversity of crops. This provides opportunities to monitor for a broad range of invasive insects and plant pathogens. The Minnesota Department of Agriculture (MDA) works with partners including the USDA Animal and Plant Health Inspection Service (APHIS) Plant Pest Quarantine (PPQ) and the University of Minnesota (U of M) to determine which insects and diseases to include in the survey. Some key criteria for including an invasive pest in the survey are:

- The likelihood of an organism reaching Minnesota in the near future (due to proximity to existing infestations or ease of movement)
- The prevalence and importance of potential hosts in Minnesota
- Climactic suitability, particularly likelihood of overwintering survival

**Survey Procedure**

The 2021 Agricultural Pathways Survey was conducted from early June through mid-September, with sites visited approximately every two weeks. Sites were in the Twin Cities and surrounding suburbs, Duluth, Mankato, St. Cloud, and Rochester (Figure 1). Primary sampling techniques included pest-specific traps and visual inspection of plants for symptoms of disease or insect injury. Insect traps were checked at each site visit, and samples were collected and submitted to the MDA Laboratory. Insects were then screened, and if found, those with national implications were submitted to the USDA for final identification.

On each site visit, a visual inspection was conducted on a portion of the plants. Plant samples were collected and submitted to the MDA Laboratory for further analysis when disease symptoms not identifiable as common garden diseases were found.

Table 1 shows the number of insects and diseases monitored by crop type in the Agricultural Pathways Survey. Table 2 shows the site types by year, and Table 3 shows the pests surveyed by year.

Insect Finds

Brown Marmorated Stink Bug

Brown marmorated stink bug (BMSB) (*Halyomorpha halys*) was first introduced to the United States in the mid-1990s from eastern Asia (Figure 2). It became a serious problem for fruit growers in the mid-Atlantic states in 2009. At present, BMSB is known to occur in most states as well as Canada. It is a generalist pest that will feed on many plants, including some economically important to Minnesota. BMSB is currently considered an agricultural and nuisance problem pest in Minnesota [www.stopbmsb.org/where-is-bmsb/state-by-state/](http://www.stopbmsb.org/where-is-bmsb/state-by-state/)

BMSB was first identified in Minnesota in 2010, and it continues to be detected throughout the state. To date, it has been detected in 29 counties. Most of BMSB finds have been in the greater Twin Cities metropolitan area. The insect is now considered established in the seven-county metropolitan area. The MDA tracks the distribution and abundance of BMSB across Minnesota in multiple ways, including citizen reports and multiple state and federally funded field surveys.

Survey Detection & Citizen Reports (2021)

Figure 4. 2021 BMSB survey locations and results.
Survey

The BMSB survey ran from May through October at 81 sites covering 26 different counties (Figure 4). There were six new BMSB detections in Rice, Dakota, Carver, and Washington counties; one new vineyard in Stearns County; and five new community gardens in Anoka, Hennepin, Olmsted, and Dakota counties. The amount of BMSB captured at most of these locations was very small, and there is little evidence that they are causing any widespread damage in these settings. Populations are building quickly in urban settings and may require implementation of integrated pest management strategies soon.

BMSB Monitoring

The MDA continues to partner with the U of M through data sharing and research. The U of M evaluates and understands the community of natural enemies that are present in agricultural settings that may have an impact on BMSB population dynamics. The MDA organizes a monitoring network for BMSB to better track its distribution and abundance. An interactive map of up-to-date BMSB detections in Minnesota is available on the MDA’s BMSB webpage: www.mda.state.mn.us/bmsb

A large increase in reports and trap catches of BMSB in 2022, including trapped nymphs, has indicated growing activity and establishment in the Twin Cities metropolitan area. The increase has been well documented with seven years of monitoring data (Figure 5 and 6). This information provides an opportunity to closely monitor the build-up of BMSB populations in urban and residential settings and its transition to agricultural settings. Detailed monitoring provides an opportunity to avoid reactive use of insecticides by agricultural producers.

In addition to monitoring BMSB, the MDA conducted a sticky card survey for Trissolcus japonicus, a non-native wasp species that parasitizes BMSB eggs that has been captured in other states that have BMSB. The MDA placed traps at 10 locations where BMSB nymphs had been detected in previous years. This is the second year of the Trissolcus japonicus survey and, while none were found, a native Trissolcus species that parasitizes some BMSB eggs was detected in both years.

Velvet Longhorned Beetle

Velvet longhorned beetle (VLB) (*Trichoferus campestris*) is an exotic beetle native to Asia and Eastern Europe with the potential to become a pest in Minnesota (Figure 7). Preferred hosts include apple and mulberry, but it has also been recovered from maple in Canada and has been found attacking and causing damage in live cherry and peach trees in Utah. Velvet longhorned beetle biology is similar to other woodboring beetles, such as the Asian longhorned beetle, but it differs in that it has the potential to infest and complete its lifecycle under dry wood conditions. Thus, the range of potential hosts could include dry cut wood with bark as well as recently cut logs.

In 2021, VLB traps were set in 29 counties at 67 orchards, campgrounds, and parks. Adult beetles were captured in five counties: Carver (first county find) Dakota, Olmsted, Scott, and Winona (first county find). Recent finds indicate that VLB is likely widely established in parts of central and southern Minnesota. No evidence of damage caused by VLB has been observed. The MDA will continue monitoring for VLB in orchards in 2022.

Disease Finds

Bacterial Canker of Tomato

Bacterial canker of tomato, caused by *Clavibacter michiganensis* sbsp. *michiganensis* (CMM), can cause spots on fruit (Figure 10), leaf wilt, stem cankers, and plant death. In 2021, tomatoes grown in community gardens, commercial vegetable fields, and high tunnels were surveyed for symptoms of bacterial canker. Samples of suspect plants were analyzed at the MDA Laboratory to determine if CMM was present.

As in previous years, infected plants found inside high tunnels had different symptoms than infected plants identified outdoors. In a field or garden, the CMM bacteria splash on rain and irrigation resulting in spots on fruit and discoloration of the leaf edges. Plants in a high tunnel are sheltered from rain and do not have fruit spots. CMM is more likely to spread on workers’ hands and tools in a high tunnel or greenhouse where plants are frequently handled for pruning, staking, and tying. The bacteria infect minor wounds caused by handling, then move into the plant’s vascular system. This results in wilt, cankers, and death of the plant.

Prior to 2015, the occurrence and distribution of bacterial canker of tomato in Minnesota was unknown. CMM has now been identified in 17 counties across Minnesota. The 2021 survey found CMM infected plants at seven sites in four counties: Ramsey, Hennepin, Benton, and Isanti. This pathogen had been previously identified at all seven sites in earlier surveys. It is possible for CMM to survive in plant debris from one season to the next after it is initially introduced. Introduction of CMM commonly occurs on infected tomato seed or tomato transplants.

For more information on bacterial canker of tomato visit: [www.mda.state.mn.us/plants/plantdiseases/cmm](http://www.mda.state.mn.us/plants/plantdiseases/cmm)

Figure 11. Counties where bacterial canker of tomato has been identified (2015 – 2021).
Tomato Brown Rugose Fruit Virus

Tomato Brown Rugose Fruit Virus (ToBRFV) was first identified in greenhouse grown tomatoes in Jordan, Minnesota in 2015. Although it was found in California in 2018, all plants at the infected sites were destroyed and the disease is considered eradicated and not present in the U.S. The primary hosts of ToBRFV are tomatoes and peppers. This virus moves long distances on infected seeds and spreads easily from plant to plant on workers’ hands, clothes, and tools. Infected plants have puckered or distorted leaves with unusual mosaic patterns in varying shades of green (Figure 12). Fruit have unusual patterns and blotches of green, yellow, or brown. Brown patches may be dry and wrinkly. In addition to affecting the marketability of tomato fruit, ToBRFV can also reduce production by causing early fruit drop and smaller fruit.

In 2021, tomatoes and peppers grown in high tunnels were surveyed for symptoms of ToBRFV. High tunnel and greenhouse production are considered higher risk for ToBRFV than field grown tomatoes due to the frequent handling of plants in indoor environments. ToBRFV was not identified during the survey.

Phytoplasma Diseases of Grapes

In 2021, the MDA surveyed vineyards for phytoplasma diseases on the USDA priority pest list. Phytoplasmas are bacteria that live within the vascular system of plants and are spread from plant to plant by sap sucking insects like leaf hoppers. Australian grapevine yellows, blackwood disease, and flavescence dorée are grape diseases caused by invasive phytoplasmas. Leaves on infected vines begin to discolor at the veins, then large sections of the leaf turn color and curl under. Leaves on red varieties turn purple. On white varieties, leaves turn metallic white to yellow. Fruit production is reduced, and clusters often shrivel and drop off. Overall vine growth is reduced. Although these diseases do not currently occur in the United States, they could be introduced on infected plant material. There are no treatments for phytoplasma infected plants. No grape vines infected with invasive phytoplasma diseases were identified in the 2021 survey.

Brown Rot of Apple

Brown rot of apple, caused by *Monilinia fructigena*, results in significant damage to apples in Europe. Several species of *Monilinia* cause brown rot in fruit trees, resulting in shoot blight, branch dieback, and fruit rot. *Monilinia fructigena* has not been found in the U.S., but a native species, *M. fructicola*, causes significant damage to plums, cherries, apricots, and other *Prunus* trees. In 2021, apples with buff-colored powdery spores characteristic of *Monilinia* spp. were found in commercial orchards in Scott County. Cultures of the suspect fungus were sent to a USDA identifier and were confirmed to be the native species of *Monilinia*. Although the native species of *Monilinia* rarely causes problems on apples, infections can occur through wounds.
